

---

Our concept focuses on monitoring hacker activity through the use of honeypot technology.

By deploying our intelligent honeypots, the platform detects attackers at an early stage and uncovers their tactics before any real damage can occur. It transforms malicious actions into valuable insights, providing a significant security advantage while ensuring that your workflow remains smooth and uninterrupted.

The system consists of four distinct devices, each functioning as an individual honeypot: an attacker machine, a honeypot, a server (representing real data), and a router that creates our isolated subnetwork.

When a port scan or unauthorized access attempt is made from the attacker machine to the honeypot, the honeypot records the activity. This information is then displayed on the monitoring dashboard, allowing users to see who the attacker is, the commands used, and what they attempted to exploit—such as ports, programs, and other components.

We are not selling new technology, as we recognize that honeypots themselves are not new. Instead, we are offering a complete product based on established methods—an integrated solution that includes everything inside a single device.

We also acknowledge that many large and small companies already use similar tools to prevent and predict cyberattacks. Therefore, our product is intended strictly for educational purposes—for universities, schools, and colleges, enabling students to clearly understand how honeypot technology works. It is also suitable for companies that aim to train their employees to use honeypots effectively and recognize hacking attempts.
